

Vector Algebra

Vector notation is designed to not just give you a point in space but a directional vector. They will usually look like $\langle 2, 5 \rangle$. This is giving you a vector that starts at the origin and continues in the direction of the (x, y) point of $(2, 5)$. Vectors can also be written in the form: $2i + 5j$. The i component is always x and the j is y .

Basic Vector Operations and Rules (let $u = \langle a, b \rangle$ and $v = \langle c, d \rangle$)

Magnitude of a vector: $|v| = \sqrt{a^2 + b^2}$; length of the vector

Addition Rules: $u + v = \langle a, b \rangle + \langle c, d \rangle = \langle a + c, b + d \rangle$

Scalar Multiplication: $cu = c\langle a, b \rangle = \langle ca, cb \rangle$

Examples of addition and subtraction with vectors, scalar multiplication:

Let: $U = \langle 2, 3 \rangle$, $W = \langle -4, 6 \rangle$

- 1) $U + W = \langle 2 - 4, 3 + 6 \rangle = \langle -2, 9 \rangle$ or $-2i + 9j$
- 2) $W - U = \langle -4, 6 \rangle - \langle 2, 3 \rangle = \langle -4 - 2, 6 - 3 \rangle = \langle -6, 3 \rangle$ or $-6i + 3j$
- 3) $2U - 3W = \langle 4, 6 \rangle - \langle -12, 18 \rangle = \langle 4 - (-12), 6 - 18 \rangle = \langle 16, -12 \rangle$ or $16i - 12j$

You Try (1): find $4U - 2W$

Unit Vector- magnitude is 1

Example of converting a vector to a unit vector: $v = \langle 2, 5 \rangle$

- 1) Find the magnitude $\rightarrow \sqrt{2^2 + 5^2} = \sqrt{4 + 25} = \sqrt{29}$
- 2) $U = \frac{1}{|v|} v = \left\langle \frac{2}{\sqrt{29}}, \frac{5}{\sqrt{29}} \right\rangle$
- 3) This would give a unit vector (length of 1) in the direction of v .

You Try(2): find the unit vector for the vector $v = \langle -1, 5 \rangle$

Dot Product

The dot product is used to find the angle between two vectors. The result will always be a scalar (a number not a vector).

Definition: if $u = \langle a, b \rangle$ and $v = \langle c, d \rangle$ then $u \cdot v = ac + bd$

Example: $u = \langle 2, 3 \rangle$, $v = \langle -4, 6 \rangle$, then $u \cdot v = 2 \times -4 + 3 \times 6 = -8 + 18 = 10$

You Try(3): $u = \langle 1, 5 \rangle$, $v = \langle -2, 1 \rangle$ solve for $u \cdot v$

Find the angle between two vectors (application of the dot product)

$$\cos \theta = \frac{u \cdot v}{|u||v|}$$

So if $U = \langle 2,3 \rangle$, $V = \langle -4, 6 \rangle$, then:

$$\cos \theta = \frac{\langle 2,3 \rangle \cdot \langle -4,6 \rangle}{|\sqrt{13}||\sqrt{52}|} = \frac{-8+18}{26} = \frac{10}{26} = \frac{5}{13}; \text{ thus } \cos \theta = \frac{5}{13}; \text{ so } \theta = 67.38^\circ.$$

On another note, two vectors are said to “orthogonal” (at a right angle or 90° apart) if $u \cdot v = 0$

You Try(4): find the angle between $U = \langle -2,1 \rangle$ and $V = \langle -4, 3 \rangle$

Finding the scalar component of u on v

An important use of the dot product is to determine the projection of one vector onto another if they share a common initial point.

If θ is the angle between vectors u and v , then the scalar component of u on v is given by:

$$\text{comp}_v u = \frac{u \cdot v}{|v|}$$

So if $u = \langle 2,3 \rangle$, $v = \langle -4, 6 \rangle$, then

$$\text{comp}_v u = \frac{\langle 2,3 \rangle \cdot \langle -4,6 \rangle}{|\sqrt{13}|} = \frac{10}{\sqrt{13}} = 2.77 \text{ to 2 significant figures.}$$

One application of this is Work which can be defined as:

$$\text{comp}_d F |d| = \frac{F \cdot d}{|d|} |d| = F \cdot d$$

Answers to You Try’s: 1) $\langle 16, 0 \rangle$ 2) $U = \langle \frac{-1}{\sqrt{26}}, \frac{5}{\sqrt{26}} \rangle$ 3) 3 4) 26.57°
